BIG DATA AND BOUNDED ETHICALITY

Yuval Feldman* & Yotam Kaplan**

Wrongdoing is ubiquitous. Media outlets constantly report an endless stream of deleterious human behavior, from sexual harassment and fraud in financial markets to corporate and political corruption. Recent developments in behavioral ethics research suggest that these ills will forever accompany human interaction due to the phenomenon of “bounded ethicality,” or people’s limited ability to conduct an objective and candid moral examination of their own actions. When evaluating the ethical implications of their behavior, individuals have been shown to be biased and to systematically underestimate or ignore the magnitude and effect of their own misconduct. Such findings have troubling implications from a law enforcement perspective. That is, if wrongdoers are able to convince themselves they are doing nothing wrong, how can regulators and policy makers ever successfully reduce or prevent misconduct? Essentially, recognizing the power of bounded ethicality reinforces the idea that destructive human behavior may be unavoidable, and that it may never be possible to reduce the systematic wrongdoing currently observed throughout society.

In response to the challenges that bounded ethicality poses, this Article explores how using big data analytics contributes to curbing both ethical bias and the results of bounded ethicality. The Article is breaking new ground in being the first to explore the intersections between the growing literature on behavioral ethics, highlighting the concept of bounded ethicality, and the scholarship and research on data-driven law enforcement.

We suggest that to combat bounded ethicality, regulators should use ethical nudges, regulatory interventions designed to improve ethical deliberation by potential wrongdoers. We show that the use of big data...
analytics is crucial for the successful deployment of such regulatory interventions, for several reasons.

First, ethical nudges must be deployed in real time, when potential perpetrators are making their decisions regarding possibly unethical actions. Big data analysis can facilitate this type of timely regulatory response in its shift from ex post inquiry to ex ante prediction. By collecting and analyzing data on the antecedents of wrongdoing, big data analytics can enable regulators to respond at opportune moments and situations, rather than engage perpetrators ex post facto.

Second, ethical nudges must be targeted rather than general. If individuals are nudged constantly, ethical nudges will lose their effectiveness due to the phenomenon of ethical numbing. By identifying the situations that breed unethicality and limiting nudges to those situations, big data analysis can ensure that people are not overexposed to ethical nudges, thereby maintaining their efficacy.

Third, ethical nudges must also be tailored to the characteristics of the specific bias that is causing unethical behavior in each specific case. Using big data analytic, together with behavioral ethics insights, regulators can collect information that will indicate the nature of the ethical bias operating in specific instances of wrongdoing, and thus be able to deploy the appropriate regulatory response.

In addition to presenting several other advantages of using big data analytics as part of the efforts to reduce bounded ethicality, this Article suggests a full menu of regulatory tools designed to improve moral deliberation and discusses the importance of big data analytics as a basis for their use.

Our analysis calls for a reorientation of existing practices of data-driven law enforcement, to make it more suited for the regulation of bounded ethicality. We show that this reorientation is also necessary for reasons related to the legitimacy of data-driven law enforcement. Data-driven law enforcement currently adopts a personalized focus, attempting to identify individuals who are more likely to commit crimes. This approach is highly problematic, raising privacy concerns and perpetuating discriminatory practices.

Conversely, the approach we advocate calls for a focus on situations, not individuals, as behavioral ethics studies show that bounded ethicality is primarily situation-driven. Therefore, big data analytics should be used to identify situations that breed unethicality, shifting the focus to individuals more likely to act badly. This use of big data analytics is less harmful to individuals' privacy, because it does not focus on personalizing legal treatments.
INTRODUCTION

Behavioral ethics is an emerging field of scientific research that studies the cognitive aspects of ethical decision-making. Behavioral ethics research highlights the concept of bounded ethicality, referring to various biases that prevent people from making an objective and candid...
ethical deliberation.\textsuperscript{2} Since people tend to interpret reality in a self-serv-
ing way, they frequently are unable to fully recognize the harmfulness of
their actions.\textsuperscript{3} Consequently, people do not generally think of themselves
as bad people and do not think of their actions as morally corrupt, even
when an objective evaluation would immediately reveal their conduct is
immoral and harmful to others.\textsuperscript{4}

Bounded ethicality is responsible for the persistent wrongdoing in
all spheres of life. Behavioral ethics research shows that people value
their own morality and will typically act unethically only if they can do
so while still maintaining a positive self-image as moral individuals.\textsuperscript{5}
Bounded ethicality means that people are often blind to their own mis-
deeds, and therefore find it easy to act unethically without experiencing
guilt.\textsuperscript{6} In this way, bounded ethicality perpetuates widespread miscon-
duct by a large proportion of people.\textsuperscript{7}

This Article highlights the potential of big data analytics as a cure
for transgressions that arise from people’s bounded ethicality. Of course,
a total solution for the problem of bounded ethicality will probably never
be available. Nonetheless, there is evidence that big data analytics has
some promising features that make it especially suited to confronting the
challenges highlighted in recent empirical works by behavioral ethics
scholars. In exploring this possibility, this Article is the first to combine
behavioral ethics research with the literature on big data law enforce-
ment. The Article thus breaks new ground by connecting two important
and trending fields of literature, and by offering novel possibilities for
regulating and reducing the most common types of wrongdoing.

The motivation for our study lies in the realization that law enforce-
ment practices must be reformed in light of behavioral ethics findings.\textsuperscript{8}

prevent people from recognizing their wrongdoing and encourage them to feel as if they are far more moral, unbiased, and law abiding than they actually are”).

\textsuperscript{7} Feldman, supra note 2, at 1 (discussing the prevalence of misconduct by ordinary people in everyday situations).

\textsuperscript{8} Id. at 88–104 (presenting the need for a new regulatory approach, designed to enhance ethical decision-making).
Research in behavioral ethics reveals the centrality of bounded ethicality as the root cause of systematic and tenacious unethical behavior. It has been shown that bounded ethicality is central to many major societal ills, ranging from sexual harassment\(^9\) and racial discrimination of employees\(^{10}\) to political corruption\(^{11}\) and systematic violations of consumer rights.\(^{12}\) Since wrongdoing is so often caused by people’s bounded ethical capabilities, a key aim of regulatory intervention should be to improve individuals’ moral deliberations.\(^{13}\)

To illustrate this point, consider first the widespread phenomenon of sexual harassment. The Me Too movement has demonstrated that sexual harassment is extremely common, often likened to an epidemic,\(^{14}\) with more than 80 percent of women in the United States reporting they have been the harassed.\(^{15}\) Research in behavioral ethics shows that the bounded ethicality of harassers is a major cause of sexual harassment and its disturbing prevalence. Specifically, harassers are too often able to convince themselves that they are not in fact harassing, but that their advances are welcomed,\(^{16}\) and that their behavior is harmless\(^{17}\) or socially acceptable.\(^{18}\) Of course, perpetrators do not usually think that sexual harassment itself is acceptable; rather, their biased ethical thinking

APPLIED PSYCHOL. 914, 914–15 (2001) (The authors report that women, as compared to men, perceive many more behaviors as harassing; this means potential perpetrators often fail to recognize the harmfulness of their behavior).

18 Tenbrunsel et al., supra note 9, at 255 (“harassers who experience ethical fading may be blind to the ethical dimensions of their actions, leading to behavior that they consider benign but that is in fact sexual harassment”).
allows them to ignore the fact that their own acts constitute harassment.\(^\text{19}\) This is the mechanism by which bounded ethicality perpetuates sexual harassment as a social reality.\(^\text{20}\) To fight sexual harassment effectively, policy makers must find ways to make it harder for perpetrators to excuse or dismiss their own behavior.\(^\text{21}\)

Bounded ethicality is similarly central to misconduct in the commercial sphere, with misrepresentation by financial advisors being a prime example.\(^\text{22}\) Financial advisors provide unsuitable advice, misrepresent facts, and engage in unauthorized activities.\(^\text{23}\) Such behaviors cause constant losses for investors, not to mention occasional calamities, such as the Enron scandal,\(^\text{24}\) or the 2008 financial collapse.\(^\text{25}\) In the United States, more than 650,000 financial advisors manage over $30 trillion in private assets for American families.\(^\text{26}\) The frequency of misconduct by those financial advisors is staggering, as many current employees of financial institutions and firms are repeat offenders who have been previously accused of violating consumers’ rights.\(^\text{27}\) Bounded ethicality is a central cause for the ubiquity of misconduct by financial advisors.\(^\text{28}\) By the nature of their occupation, financial advisors provide their clients with highly speculative information; and it has been shown that people find it much easier to persuade themselves of their own truthfulness.

when the information they are presenting is highly uncertain. Financial advisors also operate under vague and general legal standards, and studies show that this ambiguity contributes to the ability of financial advisors to excuse or ignore their own misconduct. Similarly, it has been demonstrated that people find it much easier to convince themselves they are not committing a wrong when the definition of the wrong is unclear. Financial advisors, like many employees, also often operate under distorted norms of professionalism, putting the interests of the organization above anything else, including the legitimate interests of other parties. Similarly, studies have found that people avoid experiencing guilt when they do not feel their wrong benefited them personally, but was rather committed in the name of an organization. Finally, it has been shown that people find it much easier to excuse and justify a wrong against an unknown and unrecognized target, and financial advisors often work with clients they do not know, or have never met in person. The cumulative effect of these factors helps explain the ubiquity of unethicality in the financial sector. Thus, to battle misconduct in finan-

30 Investment advisors typically operate under a fiduciary duty, understood as an obligation to give priority to their customers’ interests over their own. For a theoretical analysis of fiduciary duties, see Robert H. Sitkoff, The Economic Structure of Fiduciary Law, 91 B.U. L. Rev. 1039, 1039–42 (2011). For an analysis of fiduciary duties in the corporate context, see Oliver Hart, An Economist’s View of Fiduciary Duty, 43 U. Toronto L.J. (1993). In the case of brokers, who are not legally considered investment advisors, the legal standards are even murkier. Currently, the law has yet to precisely define the legal standard under which brokers operate, and it is not even clear if this standard is equivalent to a fiduciary duty or to some other, lesser, form of duty toward their clients. Arthur B. Laby, Implementing Regulatory Harmonization at the SEC, 30 Rev. Banking & Fin. L. 189, 189 (2010).

31 Behavioral ethics research usually discusses this issue in terms of the paradigm of moral wiggle room, see Jason Dana, Roberto A. Weber & Jason Xi Kuang, Exploiting Moral Wiggle Room: Experiments Demonstrating an Illusory Preference for Fairness, 33 Econ. Theory 67, 67 (2007).

32 For a theoretical development of this point, see Yuval Feldman & Henry E. Smith, Behavioral Equity, 170 J. Institutional & Theoretical Econ. 137, 141 (2014). For empirical evidence for the effect of legal ambiguity, see Constantine Boussalis, Yuval Feldman & Henry E. Smith, Experimental Analysis of the Effect of Standards on Compliance and Performance, 12 Reg. & Governance 277, 288 (2018).

cial markets, regulators must account for bounded ethicality and find ways to remove or reduce ethical blind spots.37

Finally, consider the effects of bounded ethicality on the behavior of elected officials, purportedly required to consider the public interest above their self-interest.38 A recent OECD report declared bounded ethicality as one of the major causes of political corruption and suggested that behavioral ethics research should be used to battle corruption worldwide.39 Research indicates that bounded ethicality is a central cause of political corruption, as officials are often unable to adequately distinguish their own narrow interests from the best interests of their constituencies.40 Thus, for example, a politician will become convinced that he or she is voting for a certain bill because of the persuasive argument of a lobbyist, rather than the prospect of future financial support from the interest group represented by that same lobbyist.41 Public servants, like all people, are often guided by mixed motives, acting for both legitimate and illegitimate reasons. Under such circumstances, behavioral ethics research shows that people are influenced by an objectivity bias,42 which causes people to mistakenly attribute their decisions to legitimate motivations and to downplay the effect of self-interest on their decisions.43 To effectually reduce corruption, policy makers must understand its cognitive sources and act to overcome them.

More generally, our perception of regulation and law enforcement must change to accommodate behavioral ethics findings and the concept of bounded ethicality. Since people’s inability to conduct an objective and candid ethical evaluation is a major source of illegal and immoral

behavior, one of the main aims of legal policy must be to improve ethical deliberation by potential wrongdoers. Regulators should therefore strive to engage directly with perpetrators’ level of ethical awareness, and act to make it more difficult for people to dismiss or ignore the harmfulness of their actions. This means regulators should aspire to target perpetrators’ awareness in real time, when the wrongdoing is being committed. Thus, we propose the use of ethical nudges, regulatory tools that encourage ethical deliberation by guiding wrongdoers towards a better understanding of their own behaviors. For example, in the case of misrepresentation by financial advisors, electronic messages may alert representatives to reconsider their statements when they contain exaggerated content. As we describe herein, similar tools are already being implemented in some contexts.

This proposed change in the perception of law enforcement, targeting bounded ethicality, calls for a shift in emphasis in current regulatory policies. This shift also presents several challenges, as regulating bounded ethicality requires new tools and abilities. We discuss these challenges here and then proceed to highlight the solutions big data analytics offer.

First, to curb bounded ethicality, regulators must be able to initiate interventions in real time, when perpetrators are making their ethical, or unethical, decisions. If misconduct originates from individuals’ bounded ethicality, regulators must engage with people’s awareness to prompt improved ethical deliberation by perpetrators. To do that, regulators need to be able to predict unethicality in order to deploy ethical nudges at the time that ethical decisions are actually being made.

Second, regulatory interventions must be targeted and specific rather than broad and general. Behavioral ethics research suggests that

54 See infra subsection II.B.2.
it would be nearly impossible to generate a general improvement in people’s ethical deliberation capabilities.\textsuperscript{55} Just as we cannot expect to solve the problems of bounded rationality and make people generally more rational, we also cannot expect to be able to solve the problems of bounded ethicality and simply produce generally more competent ethical thinkers. Instead, behavioral ethics research suggests we can improve ethical decision-making in specific instances by applying appropriate targeted interventions.\textsuperscript{56} This means that ethical nudges, designed to improve deliberation, must be presented only if and when they are truly needed. If everyone constantly encounters ethical nudges, such nudges would lose their meaning and impact. Typically, from an awareness perspective, ethical nudges must stand out to counter the phenomenon of ethical numbing, referring to individuals’ decline in moral awareness in response to repetition and routine.\textsuperscript{57} Therefore, ethical nudges must be deployed carefully and sparingly, in a way that will maximize their impact on potential perpetrators’ awareness.

Third, regulatory interventions must be tailored; that is, sensitive to the characteristics of specific cases.\textsuperscript{58} Behavioral ethics research shows that unethicality is generated by a variety of different biases that allow individuals to excuse, ignore, or justify their misconduct.\textsuperscript{59} Each type of bias calls for a different regulatory response in order to improve ethical deliberation. To achieve this goal of improving ethical decision-making, regulators must be able to choose an ethical nudge that would help reduce the specific ethical bias that causes unethical behavior in each specific case.

Fourth, behavioral ethics research shows that, in some situations, a great majority of people will choose to lie and cheat.\textsuperscript{60} Consequently, regulators can no longer focus their attention exclusively on abnormal cases and extreme lawbreakers, but must be able to regulate a much larger percentage of people.\textsuperscript{61}

\textsuperscript{55} Dolly Chugh & Mary C. Kern, A Dynamic and Cyclical Model of Bounded Ethicality, 36 Res. Organizational Behav. 85, 91 (2016).
\textsuperscript{58} See infra subsection II.B.3.
\textsuperscript{59} Feldman, supra note 2, at 1.
\textsuperscript{60} Dan Ariely, The (Honest) Truth About Dishonesty: How We Lie to Everyone, Especially Ourselves 104 (2012) (the aggregate results of the experiments and findings presented by the authors emphasizes how widespread unethicality actually is).
\textsuperscript{61} See infra subsection II.B.4.
Fifth, ethical nudges face a unique challenge, as they seek to prompt individuals to behave morally and consider the welfare of others. In contrast, traditional nudges help people act more effectively in their own favor. This motivational difference between traditional and ethical nudges means that individuals do not always have the incentives to be ethically nudged, and ethical nudges must be particularly effective in order to work.

These challenges make it particularly difficult to mitigate the effects of bounded ethicality. We argue that the key features of big data analytics make it a particularly promising tool for overcoming these issues. Big data analytics can be used to identify and characterize the antecedents of unethical behavior, and thus guide policy makers regarding the most appropriate regulatory responses. Through the integration and analysis of existing databases, policy makers and law enforcers can identify more accurately the conditions under which unethicality flourishes. By mining these datasets for patterns, we can learn to describe, in a much more finely calibrated way, the specific characteristics of prevalent wrongdoing and identify the situations in which regulation will be most effective. This will enable regulators to identify those specific situations in which targeting transgressors’ awareness and triggering moral deliberation will be most effective, and then advance the appropriate regulatory response. As we show, such a regulatory scheme can provide answers to the challenges of regulating bounded ethicality.

First, data-driven law enforcement marks a shift from ex post inquiry to ex ante prediction. That is, using big amounts of data, regulators and law enforcers are now increasingly able to anticipate unethical behavior and recognize its antecedents. This capacity is crucial if regulators are to be able to deploy ethical nudges in real time, and thus influence perpetrators’ ethical deliberation as decisions are being made.

Second, by using big data analytics, regulators can minimize their use of ethical nudges, and deploy them only if and when they are needed. This will enable the use of targeted regulatory interventions and help avoid the problem of ethical numbing and the danger that ethical nudges will lose their effectiveness if overused.

Third, big data analysis can help ascertain in great detail the characteristics of each specific instance of wrongdoing. This can help identify the behavioral mechanism responsible for the unethical conduct and al-

63 See infra subsection II.B.5.
65 See infra section III.A.
66 See infra section III.B.
low regulators to apply the most suitable type of regulatory intervention in each case. Thus, regulation driven by big data analysis can facilitate tailored regulation, sensitive to the specific behavioral characteristics of each violation.67

Fourth, big data in law enforcement signifies a shift from data focused on repeat offenders and extreme cases to data that covers the population as a whole, including those who have not previously encountered law enforcement authorities.68 This comprehensive characteristic of big data is useful for the goal of curbing bounded ethicality, as wrongdoing is committed by a substantial proportion of people.69

Fifth, research shows that the use of big data analysis can help make existing regulatory means significantly more potent, as the abundance of information facilitates an accurate and effective intervention.70 This can provide ethical nudges the extra kick necessary to induce individuals to consider the interests of others, rather than their own, as is the case with traditional nudges.71

Part I of this Article provides an introduction to behavioral ethics and explains the concepts of bounded ethicality. This Part clarifies the main findings of behavioral ethics research and differentiates this field from other branches of behavioral science, such as behavioral law and economics. This Part also elaborates on the types of bounded ethicality described in behavioral ethics research, and on its heavy social costs. Part II highlights the relevance of behavioral ethics findings for law enforcement and regulation. Its aim is to demonstrate the need for a new regulatory approach that more explicitly targets the ethical awareness of potential perpetrators. This Part surveys prevailing theories of regulation and law enforcement and reveals their inadequacies in light of behavioral ethics findings. Mainly, existing regulatory paradigms that emphasize such concepts as deterrence and legitimacy fall short once we recognize the ability of perpetrators to ignore or justify their own unethical behavior. This Part details the challenges that behavioral ethics presents for law enforcement and situates the problem of improving behavior in a world of ethically bounded actors. Part III continues by introducing the solution of data-driven regulation and highlights its advantages in the context of each of the regulatory challenges presented in Part II. Part III surveys existing practices of data-driven law enforcement and shows how these existing elements can be tweaked to regulate bounded ethical-

67 See infra section III.C.
69 See infra section III.D.
70 Brayne, supra note 68, at 981–82.
71 See infra section III.E.
ity in a more effective manner. Our proposal is based on combining the literature and practice of data-driven law enforcement with behavioral ethics research and its empirical findings. Part IV considers some of the main challenges for our proposal, especially in terms of privacy and constitutionality. We argue for a reorientation of current data-driven law enforcement practices. In particular, we show that regulation based on big data analysis should shift from its current focus on individualization and personalization to a situational focus. This will make big data law enforcement more effective in reducing bounded ethicality and less invasive of individuals’ privacy. These four sections are followed by a short conclusion.

I. BEHAVIORAL ETHICS AND BOUNDED ETHICALITY

Recently, there have been important developments in the study and conceptualization of non-deliberative decision-making. Extensive research has generated competing paradigms describing various aspects of behavior that are not regulated with full consciousness. The prominence of scholars far beyond the sphere of academia, such as Daniel Kahneman, who won the 2002 Nobel Prize, and Eldar Shafir in psychology, Richard Thaler in economics, Cass Sunstein and Dan Kahan in law, and Dan Ariely and Max Bazerman in management, demonstrates the broad acceptance of the importance of intuitive and non-deliberative aspects of human choice and behavior. One paradigm that has been popularized by Kahneman’s book, *Thinking, Fast and Slow*, is the existence of two systems of reasoning. The dual-reasoning system, which has been the subject of thousands of papers and many books, differentiates between System 1, an automatic, intuitive, and mostly unconscious process, and System 2, a controlled and deliberative process. The recognition of the significant role of automaticity in decision-making has

---

76 This paradigm has also been criticized by scholars. See Arie W. Kruglanski & Gerd Gigerenzer, *Intuitive and Deliberate Judgments Are Based on Common Principles*, 118 PSYCHOL. REV. 97, 98 (2011) (surveying some of the literature criticizing the “dual model” which separates intuitive from deliberative judgment).
played an important role in the emergence of behavioral economics and subsequently behavioral law and economics. More recently, these insights have also been central to the development of the field of behavioral ethics and to its introduction into legal scholarship.

A. Bounded Rationality versus Bounded Ethicality

Both behavioral ethics and behavioral law and economics address the role of self-interest in decision-making. However, whereas behavioral ethics examines how people are driven by self-interest even when that compels them to act unethically, behavioral law and economics offer an explanation for why people do not make decisions that are in their best interests. Behavioral law and economics propose the bounded rationality argument that because of information deficiencies, cognitive limitations, and time constraints, individuals fail to make rational decisions. As a result, people are not capable of making decisions to enhance their own welfare. In contrast, behavioral ethics proposes the concept of bounded ethicality, which focuses on people’s inability to recognize their own moral faults. Bounded ethicality clouds individuals’ judgment and prevents them from seeing how their own self-interest is subconsciously driving their actions and leading them towards unethical decisions.

To illustrate the difference between these two concepts, consider an interaction between a financial advisor and a client. According to the concept of bounded rationality, the client might have different biases that will prevent him or her from accurately assessing the value of the product offered. In effect, the clients’ cognitive limitations hinder their ability to make decisions that would best serve their long-term self-interest. Conversely, bounded ethicality addresses the actions of the advisor and the mechanisms that limit the advisor’s ability to realize he or she is deceiving the client. Here, cognitive limitations sabotage the advisor’s

---

78 Sunstein, supra note 74, at 117–21.
79 Gino, supra note 1, at 107–08.
80 Feldman, supra note 2, at 1.
84 Id. at 378.
85 Id.
86 Id.
ability to recognize that self-interest is preventing him or her from acting in an objective and professional way. Behavioral law and economics and behavioral ethics can thus be understood as studying opposing archetypes of cognitive limitations related to self-interest. Behavioral law and economics studies the ways in which our cognitive limitations hinder our ability to promote our own self-interest, while behavioral ethics is concerned with the power of self-interest to hinder our ability to engage in candid ethical deliberation.

Behavioral ethics thus calls for reorienting behavioral analysis as applied to the law. It shifts the focus from whether people are able to act rationally in their own self-interest to whether they understand that they are at fault, whether their behavior can be modified, and whether something in the situation has affected their ability to recognize their wrongdoing. Understanding these processes of decision-making and how they affect questions of motivation, autonomy, and responsibility, rather than attempting to lead individuals towards their personal optimal outcome, is at the core of this new behavioral analysis of law. In our view, behavioral insights should inform efforts by policy makers to improve people’s ethical behavior, and not only their ability to make decisions that benefit themselves. To this end, the introduction of ethical nudges offers a crucial refinement of the development of legal tools introduced by Thaler and Sunstein, by refining the use of nudge tactics to improve ethical deliberation, rather than support the calculated pursuit of self-interest.

B. The Cognitive Sources of Bounded Ethicality

Behavioral ethics literature describes several mechanisms of bounded ethicality. First, bounded ethicality can lead individuals to ignore their own misconduct or fail to recognize it as harmful. People’s ethical judgment can be bounded in the sense that biased thinking prevents them from noticing their own unethicality. For example, this can result from motivated reasoning, a process by which individuals ignore some facts and emphasize others in a way that helps them support a perception of a moral self. This concept highlights the various ways by which self-interest unconsciously shapes people’s understanding of reality, as individuals tend to interpret situations in ways that serve them

---

87 Thaler & Sunstein, supra note 82, at 6.
88 Feldman, supra note 2, at 199.
89 Gino, supra note 1, at 107–08
90 Ziva Kunda, The Case for Motivated Reasoning, 108 PSYCHOL. BULL. 480, 480 (1990) ("There is considerable evidence that people are more likely to arrive at conclusions that they want to arrive at, but their ability to do so is constrained by their ability to construct seemingly reasonable justifications for these conclusions.")
Thus, through motivated reasoning, wrongdoers can interpret situations in a way that eliminates ethical dilemmas. Consequently, perpetrators often adopt a biased perception of reality that prevents them from seeing their own wrongdoing.92

Second, biased thinking can lead individuals to excuse and justify their own wrongs rather than ignore them. A central concept here is moral disengagement, or the habit of finding ways to excuse unethical conduct, even when the perpetrator is conscious of it.93 Behavioral ethics research describes a host of such tendencies, as bounded ethicality can lead perpetrators to justify misconduct through excuses such as “he had it coming” or “it would have happened even if I hadn’t been there.” Similarly, wrongdoers also engage in moral licensing, which relies on their positive self-image as ethical individuals to justify minor deviations from ethical conduct. The observation of Greenwald and Banaji on the power of implicit judgment is particularly relevant in this context: because people love themselves, they have difficulty admitting, even to themselves, that they have behaved immorally.94

More generally, bounded ethicality is supported by people’s tendencies to overestimate their own ability to remain impartial and to accurately assess the nature of their actions and motives.95 As a result, they will often believe they are acting more ethically than they actually are.96 Chugh, Bazerman, and Banaji attribute such behaviors to an illusion of objectivity, which causes people to view themselves as more objective in comparison to others.97 This illusion hinders individuals’ ability to recognize their lapses into corrupt and immoral behaviors. These psychological mechanisms not only amplify the effect of self-interest but also tend to limit people’s awareness of the role of self-interest in determining their behavior, thereby widening the gap between people’s actual behavior and their evaluation of its ethicality.98 Moore et al. demonstrate that people often truly believe their own biased judgments and therefore fail to recognize that their behavior is problematic.99 Gino and colleagues

advance a similar view, showing that the level of control needed to behave ethically is much higher than that required to act unethically.\textsuperscript{100}

Such mechanisms allow individuals who value themselves as moral people to routinely engage in immoral behavior that is not accompanied by malice.\textsuperscript{101} Importantly, individuals cannot ignore or justify any and all wrongs. Therefore, they will act unethically, but only in ways for which they can find reasonable justifications.\textsuperscript{102}

Many behavioral ethics findings suggest a strong link between ethical blind spots and automated cognitive processes.\textsuperscript{103} That is, bounded ethicality is closely related to System 1 thinking and to intuitive decision-making processes.\textsuperscript{104} An important contribution to this line of research is offered in a recent work by Chugh & Kern.\textsuperscript{105} They focus on how automatic processes are all largely related to self-driven bounded ethicality processes.\textsuperscript{106} Along similar lines, Marquardt & Hoeger show that individuals make ethical decisions based on implicit rather than explicit attitudes.\textsuperscript{107} In examining the automatic system, Moore & Loewenstein have found that the effect of self-interest is automatic,\textsuperscript{108} and Epley & Caruso\textsuperscript{109} conclude that automatic processing leads to egocentric ethical interpretations.\textsuperscript{110} In a recent meta-analysis, Kobis and his colleagues found evidence of intuitive self-serving dishonesty, meaning that people are more likely to lie and cheat when making ethical decisions based on intuition rather than on full deliberation.\textsuperscript{111}

C. Experimental Evidence for Bounded Ethicality

The concept of bounded ethicality, as the term suggests, points to a strong link between unethical conduct and cognitive limitations and biases.\textsuperscript{112} The behavioral claim is that people truly believe their own biased ethical judgments and are not always purposefully ignoring or justifying their own wrongs. That is, wrongdoing is not entirely conscious or calculated, but is often based on implicit judgment.\textsuperscript{113} For instance, an individual who prefers a specific conclusion, such as that he or she is not committing a wrong, will often selectively, but genuinely, remember and emphasize those elements that support this conclusion.\textsuperscript{114} This section briefly presents experimental evidence for these general claims to illustrate the concept of wrongdoing that is not fully calculated.

First, consider findings regarding \textit{moral forgetting}, reported in a three-stage experimental study by Lisa Shu, Francesca Gino, and Max Bazerman.\textsuperscript{115} At the first stage of this experiment, all participants were asked to memorize a university honor code, detailing, among other things, rules for appropriate behavior in taking a university exam.\textsuperscript{116} At the second stage, participants had to complete a series of short problem-solving tasks and report their results to an examiner in order to receive monetary payment.\textsuperscript{117} Participants were paid according to the number of tasks they reported they had been able to perform.\textsuperscript{118} In reporting their results, participants were randomly assigned to one of two treatment groups.\textsuperscript{119} Participants in the first group were made to submit their task sheet forms when they asked for their payment.\textsuperscript{120} As a result, participants in this group had no opportunity to cheat, as the examiners could directly observe the quality of their performance.\textsuperscript{121} Participants in the second group were not required to submit their task sheets when asking for their payment but were instead instructed to put those forms through a shredder.\textsuperscript{122} Participants in the second group were therefore given an opportunity to cheat, and, if they choose to do so, to report success rates

\textsuperscript{121} \textit{Id.} at 337.
\textsuperscript{122} \textit{Id.}
that were higher than what they actually scored in order to receive a higher monetary payment.\textsuperscript{123} At the third and final stage of the research, all participants were asked to recall details of the honor code they had been asked to memorize at the first stage.\textsuperscript{124} The interesting finding of the research is that participants in the second group, who had been given an opportunity to cheat, were less able to remember details of the honor code compared to participants who had not been given the opportunity to cheat.\textsuperscript{125} The findings of motivated forgetting suggest that people tend to forget facts that portray them in a negative light. Thus, to reduce the potential guilt associated with unethical behavior, people's brains reduced their ability to remember rules that prohibited cheating.

A similar concept is that of \textit{motivated seeing}, explaining the effect of self-interest on visual perception. In an experiment by Balcetis & Dunning, the authors report findings suggesting that people's wishes and preferences influence their processing of visual stimuli.\textsuperscript{126} In the study, participants were shown an ambiguous figure, such as a shape that could be reasonably interpreted as either the letter B or the number 13.\textsuperscript{127} Participants systematically tended to report seeing the interpretation that promised them a reward instead of a sanction.\textsuperscript{128} Using implicit measures of perception (e.g., eye tracking, lexical decision tasks) and experimental procedures, the authors were able to show that participants were genuinely aware only of the interpretation that favored their interests.\textsuperscript{129} These studies suggest that people not only tend to interpret information in a way that favors their interests, but that their mind completely blocks interpretations which are not serving their interests. Self-interest affects not only calculated decision-making, but also preconscious processing of visual stimuli. Self-interest can thus dictate the content that the visual system will present as a basis of conscious decision-making and perception can actually change to make it easier for people to cheat and act unethically.\textsuperscript{130}

Finally, consider the study by Shalvi, Eldar & Bereby-Meyer.\textsuperscript{131} In this experiment, participants were asked to roll a die under a cup, making the results of the roll known to the participant only.\textsuperscript{132} Participants were
then asked to report the results of their rolls and were rewarded for higher rolls.\textsuperscript{133} The first group of participants was asked to roll the die once and report the result to receive payment. Participants in the second group were instructed to roll the die twice but were asked to report only the first roll.\textsuperscript{134} Arguably, there should be no difference in the payments to participants in the two groups, because they are all are equally rewarded for the results of just one die roll. However, the main finding of this experiment was that participants in the second group, that was allowed to roll twice, found it easier to falsely report higher rolls and thereby receive higher payments.\textsuperscript{135} This finding demonstrates that the decision to cheat is not fully calculated or rational, but is determined by environmental factors.\textsuperscript{136} Fully rationale and deliberate cheaters would have cheated equally under both experimental treatments and would have falsely reported to maximize their earnings. However, this was not the observed result of the experiment, as, in fact, participants in the first group cheated less, as they found it harder to lie regarding the result of their roll, while participants in the second group found it easier to lie about the result of their first roll when they could justify their lie based on their result in the second roll.\textsuperscript{137} This is because, while they might have been reluctant to say they had rolled a five when in reality they had rolled a two, when their second roll was in fact a five, it became much easier for them to rationalize reporting that they had rolled a five in the first throw.\textsuperscript{138} This finding again demonstrates the centrality of excuse and self-justification to wrongdoing and the divergence of these factors from the prediction of the rational decision-making model.

\textbf{D. The Costs of Bounded Ethicality}

The social harms caused by people’s bounded ethicality are of unimaginable magnitude.\textsuperscript{139} Bounded ethicality leads to systematic and prevalent infractions and therefore to great aggregate harms. To illustrate this point, consider the case of simple employee theft.\textsuperscript{140} We all know that stealing is wrong. Yet, people find it surprisingly easy to justify stealing small items from work, even if they would never consider stealing cash worth the same amount. In this way, people’s bounded ethical-

  \item \textsuperscript{136} \textit{Id.} at 1269.
  \item \textsuperscript{137} \textit{Id.} at 1267–68.
  \item \textsuperscript{138} \textit{Id.} at 1268.
  \item \textsuperscript{139} Gino, supra note 1, at 107.
  \item \textsuperscript{140} For an overview of the characteristics of this phenomenon and its main causes, see Richard C. Hollinger & John P. Clark, \textit{Deterrence in the Workplace: Perceived Certainty, Perceived Severity, and Employee Theft}, 62 SOC. FORCES 398, 398 (1983).
\end{itemize}
It, or their inability to make an objective moral assessment of their actions, leads to a great deal of misconduct. In fact, studies indicate that nearly 50 percent of employees steal from their employer. Such misconduct is common because employees are able to rationalize their wrongdoing as harmless or socially acceptable. Yet this supposedly mundane misdemeanor is in fact one of the most costly forms of crime, with losses for employers estimated at over $200 billion annually. The harm caused by employee theft spreads far beyond employers, as it actually results in a 10 to 15 percent increase in the price of consumer goods, costing American families billions of dollars a year. Even more surprisingly, losses related to employee theft play a major part in the bankruptcies of between 30 to 50 percent of all insolvent organizations. The reason why this form of crime is so costly is precisely because it appears relatively mundane. Because it is easy to excuse and justify, such misconduct is commonly practiced by the majority of ordinary normative people and therefore becomes extremely common. And because bounded ethicality is so common, its cumulative impact is devastating.

This process of rationalizing what seem to be mundane acts leads to a paradoxical result: unethical acts that are perceived as effectively harmless are in fact the most harmful in the aggregate because they become so common. Thus, for example, the practice of “wardrobing,” or buying an item, using it, and then returning it for a full refund, costs retailers $16 billion a year. Other “ordinary” unethical acts result in even higher costs. Accounting misconduct accounts for the loss of $40 billion a year, insurance fraud for $24 billion a year, intellectual property theft for $250 billion a year, and tax deception for over $300 billion a year. In contrast, the more “serious” crimes of car theft and burglary account for losses of $5.9 billion and $3.6 billion a year, respectively. This means

145 Mazar et al., supra note 5, at 633.

147 Mazar et al., supra note 5, at 633.

that, in the aggregate, “ordinary” employee theft can be one hundred
times more harmful, in dollar amounts, than “serious” crimes such as
burglary. Only very few people can justify breaking into someone’s
home, but a great many can excuse stealing some paper from the office.

Lab experiments show that bounded ethicality makes unethical con-
duct nearly universal under certain circumstances. In a recent meta-
analysis of studies involving more than 30,000 participants, researchers
found that people choose to lie and cheat in about 50 percent of all exper-
imental observations. What makes this finding even more troubling is
that the incentive to cheat in a lab setting is typically relatively small and
ethical standards are made explicitly clear to participants. In real life,
when possible monetary gains from dishonest behavior are significantly
higher and ethical standards are often ambiguous or vague, and ex-post
enforcement for such misconducts is limited, cheating is likely to occur
even more frequently.

In terms of its broader implications, the prevalence of bounded ethi-
cality has a devastating effect on interpersonal trust, which is the founda-
tion of a functioning society. Due to ethical biases and individual’s
limited ability to make a fully candid moral deliberation, unethical acts
become extremely common, and can thereby even become the norm.
Therefore, the existence of bounded ethicality can completely undermine
any mechanism that relies on people’s mutual beliefs in the good inten-
tions and honesty of others. If we “know” that “everybody lies” in the
marketing world or that everybody steals from work, it makes it very
difficult to trust others. Similarly, if students know sexual harassment is
the norm in universities, their faith in the educational system and its au-
thorities can be completely shattered.

II. BOUNDED ETHICALITY AND LAW ENFORCEMENT

The findings of behavioral ethics research, with its emphasis on the
ubiqutity of bounded ethicality, have deep and troubling implications
from a law-enforcement perspective. Mainly, how can the law curb
wrongdoing if perpetrators consistently convince themselves they are doing
nothing wrong? More generally, if people can subconsciously ignore,
excuse and justify their own wrongdoing, what implications does this

have for the optimal design of legal policies and institutions? Such queries make the issue of legal compliance markedly more nuanced and more serious than previously appreciated. It seems that current assumptions of law enforcement fail to grapple with unethical conduct that arises from the limited awareness of perpetrators.

A. Ethical Nudges and the New Regulatory Approach

Behavioral ethics research recognizes people’s ability to ignore their own wrongdoing. If wrongdoers often fail to understand they are committing a wrong, what can the law do to prevent them from acting badly? Traditional regulatory mechanisms based on deterrence, punishment, rewards, and expressive morality seem ineffective in light of perpetrators’ ability to justify their own unethically and their limited awareness of the full meaning of their wrongdoing.153

1. Deterrence

Current legal scholarship emphasizes deterrence as a primary means of curbing illegality.154 Within this framework, scholars study legal rules as sanctions that impose a price on certain types of undesirable behavior.155 Based on assumptions regarding rational decision-making, sanctions have been designed to incentivize wrongdoers to refrain from harming others.156 Generations of legal scholars and law and economics scholars have studied the effects of law on behavior based on the deterrence approach.157

However, in recent decades, the deterrence or cost-benefit model has been criticized on numerous grounds. Some scholars have demon-

156 Thomas J. Miceli, The Economic Approach to Law 1 (2004) (“The economic approach to law assumes that rational individuals view legal sanctions (monetary damages, prison) as implicit prices for certain kinds of behavior, and that these prices can be set to guide these behaviors in a socially desirable direction.”); Werner Z. Hirsch, Law and Economics: An Introductory Analysis 1 (1988) (“[L]aws are authoritative directives that impose costs and benefits on participants in a transaction and in the process alter incentives.”); Steven Shavell, Law Versus Morality as Regulators of Conduct, 4 Am. L. & Econ. Rev. 227, 227 (2002) (“It is evident that both law and morality serve to channel our behavior. Law accomplishes this primarily through the threat of sanctions if we disobey legal rules.”).
strained empirically the limits of deterrence in accounting for both self-reported and actual compliance.158 Others have suggested that deterrence does not work for the simple reason that people are, for the most part, unaware of the written law.159 Behavioral scholars have challenged the dominant perception that people are motivated by a fear of sanctions.160 The relative effectiveness of enforcement mechanisms versus levels of punishment in deterring transgressions remains the subject of dispute.161 Most studies suggest that the severity of punishment has only a marginal deterrent effect on individual behavioral choices.162

Behavioral ethics research provides an explanation for the failure of deterrence to curb wrongdoing. Self-perceived good people engage in motivated reasoning and often fail to recognize the unethicality of their own actions.163 Because they are blind, at least partially, to their own unethicality, they therefore have little reason to give appropriate consideration to the possibility that they will be sanctioned for their behavior.164 Thus, the role of the law as a deterrent mechanism is currently limited at best.165

Clearly, imposing harsh punishment does have value in that it can provide a clear message about the state’s approach and commitment to enforcing morality. As we suggest later, increased punishment, if implemented properly, can also heighten people’s awareness of certain problematic behaviors.166 However, ex post punishments and sanctions

164 See Adam Fine & Benjamin van Rooij, For Whom Does Deterrence Affect Behavior? Identifying Key Individual Differences, 41 L. & HUM. BEHAV. 354, 359–60 (2017) (demonstrating that people who have high moral disengagement, low self-control and low rule orientation will be less likely to respond to deterrence).
165 Bazerman & Banaji, supra note 153, at 111.
166 Daniel S. Nagin, Criminal Deterrence Research at the Outset of the Twenty-First Century, 23 CRIME & JUST. 1, 13 (1998); Feldman, supra note 2, at 69 (Exploring ways by which traditional law enforcement mechanisms can improve deliberation by perpetrators; for in-
cannot ensure compliance on their own, as they include no mechanism for ensuring engagement with the awareness of perpetrators. The study of the appropriate sanctions, with no attention to the effect of the sanctions on the perpetrator’s awareness, is of little relevance to real-world law enforcement.

Behavioral ethics offers an alternative to the economic rational choice model of crime, which holds that a potential wrongdoer will choose to behave unethically if the gain from doing so outweighs the expected sanction. Conversely, under the behavioral ethics framework, an individual will behave unethically if it is possible to do so while continuing to believe that he or she is a moral person.

Legal sanctions and deterrence policy must meet this challenge, and be designed bearing bounded ethicality in mind. From a practical perspective, this shift entails an immense challenge, as the purpose of laws and regulations applying this approach is to find potential perpetrators, rather than actual ones, and effectively engage with their state of awareness.

2. Legitimacy

Along with deterrence, legitimacy is offered as a principal rationale for compliance with the law. The rich scholarship on compliance and legitimacy posits that people obey the law because they perceive it as legitimate. The main indicator for legitimacy is usually described as procedural fairness; that is, individuals tend to obey the law if they think it is the product of a just process of legal deliberation and rule-making. Thus, when laws appear fair and legitimate, there is evidence that people shift behavior towards greater compliance and acceptance of organiza-

---

167 This is not to say that deterrence doesn’t work in curbing unethically. Some studies do support the rational choice model for ethical decision-making, see, for example, Isabel Thielmann & Benjamin E. Hilbig, Daring Dishonesty: On the Role of Sanctions for (Un)ethical Behavior, 79 J. EXPERIMENTAL SOC. PSYCHOL. 71 (2018). Nonetheless, it is important to take into account the fact that in such studies, it is made explicitly clear to participants that one choice is ethically problematic. Id. at 72–76. This is not always the case in real life contexts, where bounded ethicality can prevent perpetrators from understanding they are behaving unethically.

168 Feldman & Teichman, supra note 29, at 980, 990 (comparing the decision to commit a wrong to the decision to role a die).

169 Mazar et al., supra note 5, at 633.

tional rules in various legal contexts, as well as towards more sensitive environmental compliance and greater organizational ethicality.

The concept of legitimacy as a basis for compliance suffers from similar limitations to those discussed above in the context of deterrence. In short, there are no practical regulatory tools for ensuring that people are aware of the law and its fairness when they decide whether or not to behave unethically. While deterrence and legitimacy are perceived as fostering compliance in different ways, the effectiveness of both is still predicated on the assumption that people make deliberate decisions regarding the law. Thus, much of the current literature on legal compliance examines people’s decision-making in the context of ethical dilemmas, ignoring the possibility that people might engage in motivated reasoning and self-deception. The rich experimental literature on compliance assumes that people recognize a moral conflict and then proceed to shape their actions accordingly. This approach fails to address the fact that people may ignore the conflict to begin with, or simply reason it away.

The assumption underlying compliance theory is that people evaluate the fairness, procedural or otherwise, of the law and then make a conscious decision as to whether or not to comply. For example, Fishbacher et al. have measured levels of compliance by asking people to make a choice to either comply or behave unethically, clearly defining the choice between doing “good” or “bad.” This framing ignores the possibility that people’s bounded ethicality will undermine their ability to recognize their choice as being the “bad” one. Behavioral ethics research shows that, in reality, motivated reasoning often leads individuals to think that the choice that serves them best is also ethically permissible.

Again, these insights call for a change of tactic in law enforcement. Instead of trying to make sure that laws appear procedurally legitimate, policy makers should focus their efforts on improving the ability of potential perpetrators to appreciate that they are indeed in violation of these

175 Feldman, supra note 2, at 16–17.

176 Id.

178 Kunda, supra note 90, at 480.
laws. Of course, once this understanding is achieved, perceptions of legitimacy might prove to be important in ensuring compliance. Yet, for people who are not engaging in ethical deliberations and are not made more fully aware of the unethicality of their actions, legitimacy on its own cannot achieve compliance.

3. Ethical Nudges

The analysis of deterrence and legitimacy offered above highlights the flawed assumptions that underlie our legal system and explain the resulting failure of existing regulatory approaches to provide an adequate response to most instances of wrongdoing. Incentives-based enforcement fails to correct a large proportion of unethical actions, because “such measures simply bypass the vast majority of unethical behaviors that occur without the conscious awareness of the actors, who engage in them.”

Indeed, some researchers who focus on ethical decision-making challenge the assumptions held by most legal scholars about self-control, autonomy, and responsibility for action, which are fundamental to contemporary regulatory theory and to the operation of most enforcement measures.

The key challenge addressed by this Article is how to create a regulatory policy to deal with misconduct perpetrated with varying levels of awareness and motivation. To ensure compliance with the law, it is not enough to threaten individuals with sanctions, nor is it sufficient to ensure that laws are perceived as fair. The key to regulating misconduct is to find ways of enabling perpetrators to evaluate their actions more candidly, while taking into consideration the possible legal ramifications of those actions and the procedural fairness of legal rules. In this sense, the concepts of deterrence and legitimacy must be reexamined and redefined, as they are being incorporated into a new behavioral framework that focuses on decision-making.

In regulating conduct, therefore, it is not sufficient to increase the effectiveness of underlying incentive structures since perpetrators are not necessarily aware of them. Rather, it is more important to improve deliberation and ethical engagement by enhancing people’s ability to evaluate the relevance of the existing legal incentive structure for their own particular actions. We refer to such regulatory tools as ethical nudges, acts of intervention designed to nudge potential perpetrators towards more virtuous conduct. Such nudges have been shown to be highly effective. For example, in some settings research has shown that making peo-

---

180 Feldman, supra note 2, at 11.
181 See generally id. at ch. 4.
182 Id.
ple sign an ethical code of conduct prior to taking action can eliminate wrongdoing almost completely.\textsuperscript{183}

This goal can be achieved in several ways, and ethical nudges can take many different forms. First, to improve behavior, regulators can directly target the awareness of perpetrators, thereby eliciting more candid ethical deliberation. This can be achieved using ethical alerts, and a variety of other de-biasing mechanisms. Such regulatory tools, if designed appropriately, can address the problem of bounded ethicality by encouraging perpetrators to use System 2 thinking and override self-serving biases.\textsuperscript{184} These techniques can prompt potential wrongdoers to consider the effects of their actions, to view the situations from the perspective of potential victims, or to report their decisions to an objective third party. The choice of regulatory tool depends on the particular bias hindering ethical deliberation. Consequently, if a perpetrator engages in motivated reasoning and interprets a situation in a way that makes it difficult to see the wrongfulness of the contemplated actions, it may be necessary to alert that individual to the true nature of the situation. Alternatively, if a perpetrator is morally disengaged, in that he or she is aware of the facts of the situation, but finds ways to justify the misconduct, an ethical nudge emphasizing the victims of such misconduct or reminding the potential perpetrator of possible legal sanctions may be more effective in preventing misconduct.

Another form of ethical nudge is the use of situational design—aimed at improving ethical deliberation indirectly—by eliminating ethical blind spots and situations that lead to unethicality. Bounded ethicality is strongest in situations where people find it easy to ignore their own wrongdoing.\textsuperscript{185} Regulators’ ability to prevent such situations can prove crucial in reducing misconduct. That is, instead of engaging with perpetrators’ awareness directly through the use of ethical alerts, regulators may instead redesign problematic situations to ensure that ethical blind spots are not created in the first place.

To illustrate this alternative approach, consider again the widespread problem of sexual harassment in the workplace. Research on sexual harassment indicates specific circumstances under which sexual harassment is more common,\textsuperscript{186} such as working in male-dominated en-

\textsuperscript{183} Shu, Gino & Bazerman, \textit{supra} note 56, at 330.

\textsuperscript{185} Feldman, \textit{supra} note 2, at 2, 16, 48–49.

\textsuperscript{186} Tenbrunsel et al., \textit{supra} note 9, at 247–48 (investigating “the contextual influences surrounding sexual harassment”); Deborah Erdos Knapp et al., \textit{Determinants of Target Responses to Sexual Harassment: A Conceptual Framework}, 22 \textit{Acad. Mgmt. Rev.} 687, 709 (1997) (“[Sexual harassment] does not occur in a vacuum but, rather, in an organizational
environments or under male supervisors.\textsuperscript{187} Apparently, in such settings, individuals have found it easier to shrug off aggressive sexual behavior as harmless or acceptable. One obvious way to address this problem would be to provide sexual harassment training, which would directly increase the level of awareness of potential perpetrators. Another course of action would be to reshape the situation, thereby eliminating the circumstances in which perpetrators find it easier to ignore or excuse their own unethicality. This can be achieved, for example, by ensuring equal representation of women in the workplace or in executive positions.\textsuperscript{188}

Note that ethical nudges are related to, yet distinct from, traditional nudges, as popularized by Sunstein and Thaler. Traditional nudges are policy interventions designed to change behavior without creating economic incentives or limiting people’s freedom of action by eliminating other possibilities. They aim at improving people’s ability to make informed and rational choices that will maximize their own well-being.\textsuperscript{189} In contrast, ethical nudges are designed to encourage more ethical conduct and to reduce the harm imposed on others. The following sections offer four general types of ethical nudges, and detail the various applications of each one.

B. The Challenges for Ethical Nudges

The discussion above outlines a regulatory framework designed according to the central insights of behavioral ethics research. In practice, the applications of this regulatory approach would involve several significant challenges that are discussed in detail below.

1. Real Time Responses

Behavioral ethics research shows that misconduct originates with the bounded ethicality of individuals,\textsuperscript{190} that is, with their biased thinking environment that affects the way people behave.”\textsuperscript{190} Chelsea R. Willness, Piers Steel & Kibeom Lee, A Meta-Analysis of the Antecedents and Consequences of Workplace Sexual Harassment, 60 PERSONNEL PSYCHOL. 127, 150 (2007) (the authors study the role played by leaders and organizations in the slippery slope, giving or denying a harasser the opportunity to harass again in the future).

\textsuperscript{188} See id. at 68–69 (arguing that appointing more women executives can reduce sexual harassment); see also James E. Gruber, The Impact of Male Work Environments and Organizational Policies on Women’s Experiences of Sexual Harassment, 12 GENDER & SOC. 301, 320 (1998).

\textsuperscript{189} Thaler & Sunstein, supra note 82, at 8.

\textsuperscript{190} Feldman, supra note 2, at 2.
and limited ability to conduct a full and candid moral deliberation at the time they take action.\footnote{191 Id. at 57.}

This means that the first challenge for law enforcement is to induce awareness in \textit{real time}. In order to influence behavior and actually reduce misconduct, regulators and law enforcers must find ways to effectively engage with people’s ethical deliberation and with their real-time decision-making process.\footnote{192 Id. at 88.} This need to implant the law into people’s consciousness more effectively is a considerable practical challenge. It also represents a significant addition to the current understanding of law enforcement and compliance, which does not explicitly consider bounded ethicality and the need to engage with the moral awareness of potential perpetrators. For example, when considering deterrence, law enforcement efforts should focus not on punishing the guilty ex post facto but on ensuring that the possibility of punishment effectively triggers candid moral deliberation in real time when potential perpetrators are considering, or failing to consider, the potential harmfulness of their own actions.

2. Ethical Numbing

Behavioral ethics research suggests that bounded ethicality is in many ways an unavoidable component of the human psyche.\footnote{193 Chugh & Kern, \textit{supra} note 55, at 85.} People are ethically bound due to a long list of cognitive limitations and those cognitive limitations, together with the consequences of bounded ethicality, are here to stay. Just as it is unlikely that we will be able to remedy bounded rationality and make people generally more rational, it is similarly unlikely that we will find general solutions to the problems of bounded ethicality and will be able to make people generally more ethical. There are ways in which people’s ethical biases have many positive attributes, as their aim is to enhance people’s self-perceptions.\footnote{194 Greenwald & Banaji, \textit{supra} note 4, at 10–11.} What behavioral ethics suggests is possible is to help individuals make better and more acceptable moral judgements in specific instances by triggering more candid moral deliberation in opportune times.\footnote{195 Shu, Gino & Bazerman, \textit{supra} note 56, at 344.} This necessitates a targeted regulatory approach, whereby policy makers know when to activate regulatory interventions.

To improve ethical deliberation, regulatory intervention must be thoughtful and targeted, so as to avoid the dangers of ethical numbing.\footnote{196 Tenbrunsel & Messick, \textit{supra} note 57, at 228.} To improve deliberation by wrongdoers, policy makers must be able to deploy nudges in appropriate moments. If ethical nudges are untargeted
and used constantly, they will lose all effectiveness. Ethical alerts are more effective if they disturb rather than become part of routines. Only if ethical nudges disturb the routine can they prompt individuals to make more candid ethical deliberations. In essence, to avoid moral numbing, ethical alerts must stand out. For all these reasons, the practical challenge for any regulatory scheme that attempts to improve ethical deliberation is to be narrow and targeted, rather than general and broad.

3. Selecting Among Nudge Types

To effectively regulate unethical conduct, policy makers must be able to match appropriate regulatory responses to different cases. Behavioral ethics research shows that unethical behavior originates with many distinct types of ethical biases. Ethical nudges, those regulatory interventions designed to improve deliberation, will only be effective if they are responsive to the specific causes of bounded ethicality in each specific case.

To select the most effective intervention, regulators will need to know which cognitive mechanisms are responsible for generating misconduct in specific cases. For instance, assume a wrongdoer behaves unethically because he or she is able to convince himself or herself that the particular behavior harms no one. If this is the case, the most direct way to improve deliberation would be to alert the perpetrator to more candidly consider the possible harm caused to others. Alternatively, assume a wrongdoer commits an offense because the legal standard is ambiguous, making it easier for perpetrators to convince themselves that their behavior is permitted. In such a case, the simplest, most effective intervention is to clarify the legal rule or to nudge the perpetrator to make a more candid deliberation of its meaning. The following paragraphs offer a menu of such ethical nudges and highlight the importance of the ability to make an informed choice among them.

Behavioral ethics research shows that motivated reasoning causes perpetrators to ignore or disregard crucial facts, thus enabling them to avoid ethical conflicts instead of facing them. To overcome this mechanism, regulators could use ethical alerts to remind potential perpetrators of facts they might otherwise ignore, or to prompt perpetrators to engage in more fitting ethical deliberations. Ethical alerts are simple cues that can be used to trigger moral deliberation. Placing such ethical reminders at crucial junctures of possible misconduct can significantly lower the risk of wrongdoing. Thus, upon placing a request for office supplies on a company’s computerized system, an employee may be reminded that

---

197 Feldman, supra note 2, at 4–5.
198 Kunda, supra note 90, at 480.
companies regularly go bankrupt due to employee theft. Such measures can be highly effective. For example, in a recent meta-analysis, Kobis and colleagues show that intuitive dishonesty disappears if perpetrators are reminded of potential injuries to victims. That is, when making ethical choices, intuitive thinking leads people to reach self-serving decisions, but only when no specific individual is assumed to get hurt. Prompting perpetrators to consider the case of a specific potential victim can improve conduct even if decision-making remains intuitive rather than deliberate. Similarly, employees may be reminded that stealing is wrong, that office supplies cost money, that consumer goods cost 10 to 15 percent more due to employee theft, that employee theft is a major societal issue, costing ten times more than street crime, and that it is a crime and punishable by severe fines. Behavioral ethics research has shown that such reminders can significantly improve behavior in varied contexts. Alerting potential perpetrators to such facts can trigger ethical deliberation and make it more difficult for them to dismiss employee theft as ethically weightless.

Thus, in some cases, just reminding perpetrators of possible legal sanctions may be the most effective route, while in other cases it may be more productive to remind them of the injuries their actions can cause others. Note that such reminders may also refer to the potential penalty for violation of duty or a breach of the obligation to signal the true value of a good. Adding references to legal sanctions may help people recognize that their true self-interest lies in overcoming their tendency to deceive themselves.

Still in other cases, it may make the most sense not to remind individuals of any specific outcome or fact, but simply to prompt them to

---

201 Id.
202 Bandura, supra note 57, at 203 (showing that people find it very difficult to cause harm to an identified victim, due to the “power of humanization”).
204 For example, it has been shown that unethically is more common when individuals are mindless of their own ethical standards; if they are reminded of these standards, unethicality subsides. See Mazar et al., supra note 5, at 635.
205 Yuval Feldman and Eliran Halali, Regulating “Good” People in Subtle Conflicts of Interest Situations, 154 J. Bus. Ethics 65, 66 (2017) (showing that reminders with ethical content and reminders regarding possible sanctions can yield similar effects in improving behavior).
engages independently in System 2 ethical moral deliberation.\textsuperscript{206} This can be achieved, for instance, by directing people’s attention to ethical symbols or messages. Studies have shown that individuals are less likely to act badly after reading morally laden texts, even short ones.\textsuperscript{207} Such measures are designed to prompt potential wrongdoers to consider the effects of their actions, to view situations from the perspective of potential victims, or to report their decisions to an objective third party. De-biasing tools employ a variety of cognitive-based techniques to overcome biased thinking and non-deliberative choices and make it possible for people to engage more fully in moral deliberation.\textsuperscript{208}

These goals can be achieved through mechanisms that encourage reflection and self-awareness. Reflection can be achieved directly, by forcing individuals to take a few extra moments to consider the implications of their actions. This can be especially useful in curbing routine unethicality and discouraging work-related misconduct. For example, upon making sales of certain types, financial advisors may be prompted to take a moment to consider the deal they are offering. JPMorgan Chase routinely sends electronic warnings to its traders reminding them to make sure they are remaining within the boundaries of the personal trading rules.\textsuperscript{209} These measures alert employees to engage in System 2 thinking before completing the task at hand.\textsuperscript{210}

Similarly, to curb misconduct by sales representatives, tailored generated alerts might occasionally require the sales representatives to record face-to-face meetings or phone calls. Alternatively, sales representatives could be required to produce written protocols, report their actions to a colleague or a supervisor, or to share more information with their clients. Such prompts can serve as a disruption of the professionals’ routines, encouraging them to use their System 2 thinking and gain a different perspective on their situations.

Accountability mechanisms are also a highly useful form of de-biasing, whereby individuals are asked to explain the reasoning for their de-

\textsuperscript{206} See Shahar Ayal, Francesca Gino, Rachel Barkan & Dan Ariely, \textit{Three Principles to REVISE People’s Unethical Behavior}, 10 Persp. Psychol. Sci. 738, 739–40 (2015). Here, the authors offer their REVISE system, which stands for REMinding, Visibility, and SELF-engagement. Under this three-step approach, first, individuals are reminded of the need to engage in moral deliberation. Second, people are made aware of their own visibility: the fact that their actions are being observed by people who know them. Finally, this approach calls for moral self-engagement, aiming to minimize the gap between people’s self-perception of morality and their actual conduct.

\textsuperscript{207} Mazar et al., supra note 5, at 635–36.

\textsuperscript{208} Jolls & Sunstein, supra note 184; Feldman, supra note 2, at 58.

\textsuperscript{209} Haugh, supra note 50, at 712, 736.

\textsuperscript{210} Id.
This tool is useful in a variety of situations, because the mere act of justifying one’s actions, particularly in writing, prompts reconsideration. First, merely articulating a justification can prompt System 2 thinking, which, by itself, can sometimes overcome ethical biases. Second, people’s awareness of the possibility that their written reports may be read by somebody else can also trigger caution and deliberation. Importantly, the benefit of accountability reports is manifest even when they are not actually read. The very requirement of writing them suffices to reduce wrongdoing, as it makes it significantly more difficult for perpetrators to ignore or excuse their own actions.

Accountability mechanisms may prove especially useful when wrongdoers operate under a veil of anonymity, are confident that their wrongdoing will not be discovered, or do not know the potential victims of their actions. Behavioral ethics research indicates that misconduct is especially common when there is no single identified victim, but rather many unidentified ones. This is because moral deliberation is often triggered by personal interaction. Accountability mechanisms can substitute for such interaction when it is otherwise missing.

Declarations of various types also offer opportunities to mitigate the effects of bounded ethicality. Declarations include any measure prompting individuals to state their commitment to a code of conduct, to ethical behavior generally, or to adherence to a legal standard. Such speech acts have been shown to trigger moral deliberation in many situations. A simple example of the use of declarations is found in the context of corporate governance or fiduciary duties. For example, before important votes are made, directors and executives could be required to sign declarations stating they are aware of the legal standards under which they operate, that they know what types of conflicts of interest they are obligated to disclose and that such conflicts are not present. Such declarations serve a dual purpose. First, according to behavioral ethics research, actively declaring adherence to the legal standard in writing can reduce unethical behavior. Requiring people to actively declare their intentions prevents them from downplaying the omissions of important facts or excusing themselves for telling passive lies. Requiring a

213 For discussion on the use of declarations, see Feldman, supra note 2, at 199.
214 Id. at 200.
declaration changes the status of the unethical conduct, making it much less likely that executives will fail to announce a conflict of interest.217 Second, from a legal perspective, signing a declaration reminds people that they can be prosecuted for perjury. Reminders of legal consequences have been shown to be effective in preventing even subtle conflict of interests.218

The different types of ethical nudges can all improve ethical deliberation in relevant cases. Behavioral ethics research offers a large assortment of regulatory tools that might be helpful in reducing misconduct in different situations. The crucial point is that, to effectively combat unethicality, regulators must be able to make informed choices and match the appropriate regulatory responses to different situations and types of misconduct.

4. The Scope of Regulation

Behavioral ethics research shows that unethical behavior is not confined to any specific segment of the population comprised of particularly malevolent individuals.219 Rather, unethical behavior is nearly universal and is commonly practiced by the majority of ordinary people.220 Thus, lab experiments show that bounded ethicality makes unethical conduct nearly universal under certain circumstances.221 In a recent meta-analysis of studies involving more than 30,000 participants, researchers found that people choose to lie and cheat in about 50 percent of all experimental observations.222

These facts present an immense challenge from a law enforcement perspective. To curb unethicality, it is not enough to identify and punish extreme divergences from prevalent moral and legal norms. Instead, regulators should adopt a broader perspective and more seriously consider the structural sources of systematic and persistence wrongdoing by “ordinary” people.223

5. Willingness to be Nudged

Another challenge in regulating bounded ethicality relates to people’s incentives and willingness to be nudged. Ethical nudges are different from regular nudges and require additional persuasive force. *Traditional nudges*, following the model proposed by Tahler and Sun-

---

218 Feldman & Halali, *supra* note 205, at 65 (showing that reading a text about possible punishment for corruption caused experiment participants to behave more ethically).
219 Ariely, *supra* note 60.

221 Gerlach et al., *supra* note 149, at 11–13.
222 Id.
stein, aim to help people overcome the cognitive biases which prevent them from promoting their own self-interest.\textsuperscript{224} In contrast, ethical nudges aim to help people engage in more candid moral deliberation, and consider the interests of others.\textsuperscript{225} Therefore, if ethical nudges are to succeed in combating bounded ethicality and improving ethical decision-making, they must be more forceful and more difficult to ignore or downplay than traditional nudges. Ethical nudges work in opposition to people’s natural incentive system, and not in support of it, and therefore require additional support in order to be effective.

Therefore, a “naked” ethical nudge will not always be potent enough to cause people to be aware of the ethical implications of their behavior, and such nudges may need to be reinforced or accompanied by an external legal threat.\textsuperscript{226} For that reason, legal sanctions designed in accordance with nudge approach insights could prove most effective. Such instruments, while reminding people of their unethical tendencies, will also draw their attention to the potential legal consequences of their unethical behavior. When functioning as nudges, the legal instruments should be designed to focus less on changing people’s cost-benefit calculation and more on increasing their awareness of the full implications, including legal ones, of their wrongdoing.

Therefore, in addition to the soft regulatory measures mentioned above, bounded ethicality can be regulated through more traditional means, if those are adjusted appropriately. That is, in some cases, the most effective way to improve ethical deliberation is by increasing sanctions and enforcement efforts, if this is done in a way that will effectively change the ethical deliberation of potential perpetrators. Making perpetrators consider the fact that punishment is more likely, or more severe, can sometimes be the best way to improve their moral awareness.

In making this observation, our approach helps remedy an additional limitation of the current literature, wherein nudges are seen as moving on a separate track in comparison to the classical command and control approach to regulation.\textsuperscript{227} Nudges are usually developed as extra-legal instruments and are seen as competing with more traditional command and control legal interventions.\textsuperscript{228} Our argument is that in ethically

\textsuperscript{224} Thaler & Sunstein, supra note 82.
\textsuperscript{225} Feldman, supra note 2, at 198–99.
\textsuperscript{226} Id.
problematic situations, ones which could be termed societal blind spots, traditional legal instruments should be seen as a type of nudge, operating to improve deliberation and overcome biased thinking.

Importantly, this may result in a regulatory focus quite different from what we currently observe. Behavioral ethics research shows that unethicality is most prevalent in situations where legal standards are vague, or misconduct is manifested in subtle, rather than obvious, violations and without identifiable victims. Therefore, enforcement should be targeted at situations which constitute societal blind spots, where many more people are likely to engage in wrongdoing, as opposed to clear-cut examples of misconduct in which far fewer people are likely to engage.

III. The Promise of Big Data Regulation

Recent years have witnessed an unprecedented increase in the use of big data as a means to improve prediction and decision-making. Big data analytics are already being employed by a wide range of organizations, from finance and healthcare to law enforcement. As eloquently put by Julie Cohen, big data is both a technology and a process. The technology involves information processing hardware able to analyze vast quantities of data in very short times. The process entails the use of the technology to identify patterns in the data, establish data-driven predictions, and apply them further. The product of this procedure is an extreme form of amalgamated knowledge. Big data analytics necessitates large amounts of information, often measured in petabytes and consisting of tens of millions of distinct observations. Big data typically involves rapid data processing from disparate sources, merging information from previously separate databases. Current applications of big data include spam and fraud detection, credit score assignment, insurance pricing, as well as data-driven policing and law enforcement.

238 Id.
the context of law enforcement, big data is used for a wide range of purposes, including individual and geographical predictions of gun violence\(^{239}\) and other serious crimes.\(^{240}\)

This Part explores the advantages of big data analytics in terms of its ability to curb the ills of bounded ethicality. We propose a use of big data never before developed in the literature, and still underused by regulators. We propose the use of big data not only in policing efforts designed to prevent severe crimes, but mainly for predicting other types of misconduct which arise not from violent tendencies, but from the bounded ethicality of potential perpetrators. We show that the characteristics and advantages of big data regulation make it particularly suited to achieving this goal. In the following sections, we highlight some of the new capabilities that big data analytics can offer to policy makers, as described in the growing literature on data-driven law enforcement. We then show that these newly found abilities can help address the challenges raised by bounded ethicality, as described in Part II above.

A. Predictive Regulation

The proliferation of big data analysis represents a paradigm shift in the general approach to the use of information. In the past, information was gathered and analyzed after the fact in response to past events, and not in anticipation of future developments.\(^{241}\) In the context of law enforcement, this shift represents a change in focus from investigation efforts after a crime has been committed to the effort to predict misconduct before the fact.\(^{242}\)

Using big data analysis to help predict misconduct before the fact provides the tools needed for dealing with bounded ethicality and engaging with the awareness of potential perpetrators in real time. If regulators are increasingly able to produce reliable predictions regarding possible misconduct, they can trigger deliberation by possible wrongdoers before they act and offer alerts reminding them of the effects of their behavior or of possible sanctions in real time. Users of alert-based systems, whether regulators or potential perpetrators themselves, can receive real-time notifications when variables that are predictive of misconduct appear in the data. This is made possible by the high frequency of observations and the

\(^{241}\) Brayne, supra note 68, at 978.

\(^{242}\) Ferguson, supra note 64, at 368.
speed of data processing. The move towards data-driven enforcement thereby supplies, for the first time, the basic framework necessary for facing the regulatory challenge posed by bounded ethicality.

B. Targeted Regulation

Data-driven law enforcement allows regulators and policy makers to focus their efforts and initiate regulatory interventions that target specific risks and behaviors. This represents a shift from a random check mentality to a targeted intervention approach. That is, instead of deploying enforcement efforts randomly, law enforcers can use data analysis to direct their activity towards the focal points of criminal activity.

In the context of bounded ethicality, this newfound ability is crucial for overcoming the danger of ethical numbing discussed above. To improve ethical deliberation, regulatory intervention must be targeted and specific, rather than general and broad. For example, ethical alerts are effective only if they are targeted and rare, rather than routine and constant. If everyone is randomly bombarded with ethical messages, those messages will quickly lose their meaning and impact. More generally, targeted intervention is necessary, as it is almost impossible to generate a general, rather than a temporary, improvement in people’s ethical capacities. Big data analysis offers a crucial advantage here, as it facilitates a regulatory scheme that only becomes operative when analysis of background information indicates that its involvement is necessary.

C. Tailored Regulation

Big data analysis offers an abundance of information regarding multiple observations. This information can guide policy makers when choosing the most appropriate regulatory response for each specific case. In this, the advantages of data-driven law enforcement can provide tools to overcome the challenge of choosing the right tools to effectively trigger deliberation and address bounded ethicality. This will be crucial in determining the most appropriate legal response, according to the nature of the ethical bias preventing candid deliberation.

There are two primary ways to use data analysis for uncovering the cognitive sources of unethicality. First, these cognitive mechanisms might be observed directly through big data analysis of existing cases of

243 Brayne, supra note 68, at 978.
244 Id.
245 Shu, Gino & Bazerman, supra note 56, at 330 (showcasing the phenomenon of “ethical depletion” through four experimental studies).
246 Id.
247 Greenwald & Banaji, supra note 4, at 10–11.
248 Chugh & Kern, supra note 55, at 85.
249 Brayne, supra note 68, at 976, 979.
misconduct. Big data analysis can provide a plethora of information on specific cases of misconduct, in a way that will enable regulators to devise the most appropriate regulatory response. As mentioned above, behavioral ethics research highlights the great diversity of enforcement means, and their suitability for different types of situations and for different types of ethical biases. For example, big data analysis could help clarify whether the likely offender in a given situation is driven by lack of ethical motivation or by lack of ethical awareness. Situations in which many of the likely transgressors are first-time offenders are more likely to be characterized by ethical blind spots relative to situations in which the transgressor is a repeat protagonist, making the possibility of unfamiliarity with the ethical problem of the behavior less likely. Moreover, using big data, we can also learn the transgression history of the most common transgressors and recognize the most suitable ethical nudges. Essentially, the history of the violations of the typical transgressor could be used to generate better predictions not just of the situational characteristics where we expect increased levels of unethical behavior, but also of the characteristics of the interventions which will be effective, based on their past efficacy across different situations.

Second, policymakers may be able to determine indirectly which mechanism is operative by using big data analysis together with an approach of experimental regulation.250 In the first stage of this experimental approach, different interventions, designed to overcome different types of biases and chosen from a large menu of mechanisms used to improve deliberation, will be deployed randomly. In the second stage, big data analysis will be used, for a second time, to evaluate the effectiveness of the different measures that were used and find those that proved most effective. This information, together with behavioral ethics research findings, can help policymakers infer the cognitive sources of unethicality and fine tune the type of regulatory intervention going forward.

Randomized content can use the protocols of experimental design and their varying effects using big data analysis. After randomized messages are deployed, big data analysis can provide insights into the effectiveness of each one. Thus, in some cases, reminding perpetrators of possible legal sanctions may be the most effective route, while in other cases, it may be more productive to remind them of the harms their actions can cause others. Note that such reminders may also refer to the

250 The more common term is experimental legislation, see Sofia Ranchordás, The Whys and Woes of Experimental Legislation, 1 THEORY & PRACT. LEGIS. 415, 415 (2013), but the term experimental regulation is also mentioned frequently and fits under the same analytical framework. Id. at 415. In both cases, the term refers to the idea that policymakers should aspire to evaluate the effects of legislation or regulation either prior to or after their implementation. Id. at 417.
potential penalty for violation of a duty or a breach of the obligation to signal the true value of a good. Adding references to legal sanctions may help people recognize that their true self-interest lies in overcoming their tendency to deceive themselves.251

D. Integrated Datasets

An important feature of big data is the integration of data from previously separate institutional sources.252 Law enforcement has always been data-driven to an extent. That is, police have traditionally used limited data sets, documenting finger prints, past convictions, or other relevant information.253 The move towards big data entails the merging of information from multiple sources and its systematic and integrated analysis.254 Such an integrated system allows users to track disparate data points in relation to one another and study correlations between data points originating in different datasets.

The move towards integrated data is especially relevant in light of behavioral ethics findings. Behavioral ethics research emphasizes that misconduct and unethicality do not originate solely with abnormally malevolent individuals, but also with ordinary, respectable people.255 This means that an effective regulatory scheme requires information beyond the narrow focus of the documentation of the actions of repeat criminal offenders. Rather, to prevent unethical conduct, law enforcers and regulators will need access to information regarding the antecedents of misconduct by all people. This accords with the move towards integrated data.256 Traditionally, law enforcers used datasets that include information on individuals who have previously been arrested or convicted of crimes.257 The recent move towards big data law enforcement entails a departure from this tradition, in favor of the inclusion of information on those with no prior contact with law enforcement authorities.258 Policy makers can also now regulate people with no prior encounters with the law, which is crucial in light of the understanding that bounded ethicality is universal.

251 Feldman & Halali, supra note 205, at 65 (showing that reminders with ethical content and reminders regarding possible sanctions can yield similar effects in improving behavior).
252 Ferguson, supra note 64, at 353.
254 Brayne, supra note 68, at 993.
255 Ariely, supra note 60.
256 Ferguson, supra note 64, at 353.
257 Id. at 351.
258 Brayne, supra note 68, at 992.
Such an integrated approach can be illustrated through recent work by Cantalupo & Kidder, who utilized the latest advances in data availability to analyze and categorize sexual harassment by university faculty members.\(^{259}\) They use a database drawn from media reports,\(^{260}\) federal civil rights investigations by the United States Departments of Education and Justice,\(^{261}\) lawsuits by students alleging sexual harassment,\(^{262}\) and lawsuits by tenure-track faculty fired for sexual harassment.\(^{263}\) More generally, many types of databases are now available for integrated, data-driven law enforcement; any dataset documenting and recording misconduct or dispute can be a relevant source of information.\(^{264}\)

First, databases currently used and maintained by law enforcement agencies can prove helpful in identifying patterns of unethicality.\(^{265}\) Existing law enforcement datasets have grown increasingly rich and detailed,\(^{266}\) now offering data points measured in the trillions even before the move to integrated datasets.\(^{267}\) These sources include datasets compiled by law enforcement agencies themselves,\(^{268}\) as well as databases compiled by private companies to be used by law enforcement agencies.\(^{269}\) Analyzed correctly, this currently available data can prove crucial in identifying and characterizing the exact details of situations that breed unethical conduct.

\(^{260}\) Id. at 705.

\(^{261}\) Id. at 715.

\(^{262}\) Id.

\(^{263}\) Id. at 728.

\(^{265}\) Id. at 181–82 (describing recent developments in the accessibility variety of data offered by existing law enforcement datasets).

Second, datasets maintained by regulators or consumer protection agencies may also prove useful. For example, in the context of financial regulation, the Securities and Exchange Commission, the Office of the Comptroller of the Currency, and other regulatory bodies hold extensive records on unethical behavior, as do the Federal Trade Commission’s Bureau of Consumer Protection and other bodies dealing with consumer complaints.\textsuperscript{270} Mining the information currently held by those institutions will enable us to characterize the types of situations under which unethical conduct seems to flourish. After such situations are identified, they can be targeted by regulatory measures that either encourage moral deliberation or hold accountable those responsible for creating these situations.

Third, private commercial actors may also maintain databases that could prove useful for our purposes. Thus, financial institutions keep extensive records, directly and indirectly documenting the actions, preferences, and behavior of both employees and consumers.\textsuperscript{271} Similar datasets are maintained and used by retailers, pharmaceutical companies, and technology firms.\textsuperscript{272} Some private companies, especially in financial markets, are already implementing situational regulation of their employees. For example, JP Morgan Chase provides ethical reminders to employees, warning them when they are approaching the limits of legitimate business practices. Such warnings are based on “predictive monitoring” algorithms and attempt to prevent wrongdoing before it occurs.\textsuperscript{273} This type of mechanism, which is based on big data analysis, is now being adopted by other financial institutions.\textsuperscript{274} The information collected by JP Morgan Chase and similar institutions can be used as another source of information for a larger big data regulatory scheme, barring proprietary considerations.

Fourth, valuable information about disputes can be gleaned from online dispute resolution (ODR) records. Since the 1990s, online markets have developed their own dispute resolution systems operating along-

\begin{thebibliography}{9}
\bibitem{271} \textit{Id.}
\bibitem{273} Haugh, supra note 50, at 712, 736.
\bibitem{274} Credit Suisse is developing a compliance program with Palantir Technologies, a Silicon Valley tech company focused on data analysis for police and intelligence services; Jeffrey Vögeli, \textit{Credit Suisse, CIA-Funded Palantir to Target Rogue Bankers}, BLOOMBERG (Mar. 22, 2016), https://www.bloomberg.com/news/articles/2016-03-22/credit-suisse-cia-funded-palantir-build-joint-compliance-firm.
\end{thebibliography}
side, and sometimes instead of, more traditional systems of adjudication. These new systems manage an enormous volume of disputes, which are usually fully documented online. Tapping into these datasets would enable an analysis of those situations that typically give rise to legal disputes following some type of misconduct. Relevant datasets include those maintained by eBay’s Resolution Center, or any other major online sellers. The analysis of the information might show which types of products or services are more likely to generate disputes. From a legal perspective, there is currently no difference between misrepresentation in selling a used car or in selling a used toy. However, from a behavioral perspective, such differences can be expected to exist, and some transactions, for example, those with more ambiguous definitions of what needs to be revealed to the buyers, are likely to lead sellers to more readily engage in motivated reasoning and justify or ignore unethical behavior. The use of big data analysis can reveal such trends, which will allow for the deployment of appropriate regulatory tools.

Fifth, general use databases can also contain much detailed information about situational wrongdoing and circumstances that lead to unethicality. For example, Google search records have proven valuable in uncovering patterns of human choice and behavior in a variety of contexts. Online behavior patterns can be used to determine those settings that tend to encourage dishonesty.

E. The Strength of Data-Driven Interventions

A final relevant feature of data-driven law enforcement is its increased effectiveness. Regulatory interventions based on big data analysis are recognized as more potent, since their use is much better guided than traditional enforcement steps. This can be crucial in improving

the effectiveness of ethical nudges and facilitate a much necessary advance in regulating bounded ethicality.

As mentioned above, improving moral deliberation is a particularly tricky task. Traditional nudges are aimed at helping people make better decisions for themselves. As such, nudges are aligned with the interests of the individuals being nuded, and are therefore easy to accept. Conversely, ethical nudges are designed to make people ignore their own self-interest or consider the interests of others. Therefore, people encountering ethical nudges might object to or reject them. The same mechanisms of bounded ethicality that led to misconduct in the first place can now be used as people ignore ethical nudges and their messages. For this reason, it is crucial that ethical nudges be made as effective as possible. Using big data analysis has been proven highly effective in achieving this goal.

IV. REORIENTING BIG DATA LAW ENFORCEMENT

Whatever we might think of it, big data law enforcement is already here, and is here to stay. The practice of using big data is already deeply entrenched in existing law enforcement procedures. To give one example of this trend, consider the case of Palantir Technologies, a private software company specializing in big data analytics. Palantir, founded in 2004, is just one of the major big data platforms currently used by law enforcers in the United States. Palantir customers include the Central Intelligence Agency (CIA), Federal Bureau of Investigation (FBI), National Security Agency (NSA), United States Department of Homeland Security (DHS), United States Immigration and Customs Enforcement (ICE), as well as police departments in major American cities such as New York and Los Angeles.

This prevalence of data-driven law enforcement has raised important legitimacy concerns. Mainly, commentators have voiced objections

Rev. 1, 14–15 (2003) (showing that law enforcement agencies are already utilizing big data analysis in a variety of contexts and arguing it would be unrealistic to expect these practices to stop).}
to this emerging form of law enforcement based on privacy and autonomy concerns, arguing that law enforcement based on big data may violate citizens’ Fourth Amendment rights. We believe that these objections to the use of big data in law enforcement are well-reasoned, pointing out the very real possibility that big data analytics grant too much power to governments, power that will eventually be abused. Scholars have similarly commented that the use of big data analysis by policy makers can perpetuate existing discriminatory patterns by mimicking them. We therefore believe that this trend, which currently seems inevitable, must be accompanied by the development of significant safeguards, designed to prevent abuse.

In this framework, we argue for a reorientation of current practices of big data law enforcement, and a rethinking of its goals and operations. In particular, we show that if big data law enforcement makes the regulation of bounded ethicality its main goal, as we propose, this can help mitigate some of the legitimate concerns regarding the use of big data analytics by law enforcers. This is true for two main reasons. First, to overcome bounded ethicality, governments do not need to gather information at the personal level. Unlike the use of big data in other contexts, such as the prevention of serious crime, the goal of government intervention is not to single out exceptionally malevolent individuals, but to identify the conditions that lead to ethical biases by ordinary people. This means that privacy concerns are somewhat less alarming in this context, as information need not be attached to specific individuals. Similarly, concerns regarding the perpetuation of prejudice and discriminatory practices is less troubling, again because big data analysis is used to produce situational predictions rather than personalized ones.

Second, to regulate bounded ethicality, governments should make greater use of softer regulatory tools, designed not to punish, but to assist potential perpetrators engage in more candid ethical reflection. Since the regulatory intervention is significantly gentler, concerns regarding the harms caused to citizens through state-initiated aggression or violence are somewhat mitigated. Importantly, these points are not to be taken to mean that data-driven law enforcement does not raise significant con-

291 Daniel J. Solove, *Digital Dossiers and the Dissipation of Fourth Amendment Privacy*, 75 S. Calif. L. Rev. 1083, 1089 (2002) (highlighting the risk to privacy in a world in which personal data is increasingly held by third parties, and not by the individuals who own this data).

Rev. 671, 671–72 (2016) (showing that the quality of algorithmic decision-making critically depends on the data on which it operates; if the data reflects prior biases and prejudices by policy makers, those biases will be reflected in the results of the algorithmic analysis).
cerns. We only argue that these concerns are somewhat mitigated in the framework we propose aimed at regulating bounded ethicality, and that current practices of digital law enforcement must be reoriented to address these concerns. We first present the existing personalized law approach to big data, and then continue by presenting the advantages of our proposed situation-based approach.

A. The Existing Personalized Law Approach

Big data law enforcement is currently closely tied to the concept of personalized law, which involves more nuanced legal responses tailored to the personal characteristics of specific individuals. The current thinking is that the natural development of big data analysis, and law enforcement generally, is towards a more personalized future, where enforcement efforts will be directed towards specific individuals.

The personalized law approach therefore upends the fundamental feature of the legal system: that the law treats all individuals equally and thus aspires to be objective and impersonal. Traditionally, many legal doctrines are based on objective standards of behavior and set general criteria against which to measure each individual’s conduct. For instance, in tort law, the standard of the reasonable person sets a uniform requirement for appropriate care and caution. Similarly, contract default rules seek to recreate the presumed intentions of the typical contracting party. These “one size fit all” standards structure the law according to some general and objective point of reference.

Recently, scholars have started to question this basic framework and to call for the more personalized application of legal standards. They argue for the use of big data analysis to set legal standards that are tai-

295 Id. at 365 (“To solve crimes, law enforcement must not only collect information, but also identify and link individuals to their accumulated data. In short, data must be connected with identifiable human beings.”).
299 Porat & Strahilevitz, supra note 296, at 1418.
lored more precisely to each specific individual. Thus, the actions of a tortfeasor should not be measured against the general and objective standard of the “reasonable person” but rather against that of a reasonable self. That is, the court should be asked to verify whether or not the tortfeasor behaved in a way that can be considered reasonable for him or her, considering all personal abilities and limitations. Scholars have also pointed out that this approach is not entirely alien to existing legal practices and, in fact, has always existed alongside the traditional position based on an objective and impersonal approach. Given the much greater availability and verifiability of information about individuals today, these scholars advocate that the balance should now tilt towards more finely calibrated subjectivity.

The personalized law approach uses big data to discern individual characteristics and then to apply a more nuanced type of law tailored to the needs and abilities of specific individuals. Research studies have shown that personality traits can be discerned from the analysis of readily available information, such as people’s smartphone usage patterns or shopping history. On the basis of this information, regulators can construct person-level psychological profiles and subsequently apply legal standards that would offer a good fit at the individual level. Thus, regulators can identify individuals’ psychological profiles in order to predict their tendencies towards bounded ethicality and target specific enforcement efforts accordingly. Police forces throughout the United States are already employing big data analytics in order to better identify suspects.

In criticizing this literature, we suggest that the personalized law approach suffers not only from legitimacy concerns due to its costs with respect to privacy and equality, but that it is also poorly calibrated for the regulation of unethical behavior as a practical matter. The main reason for this is the insufficiency of interpersonal variation as a predictor of unethicality relative to the proven importance of situational factors.

1. Interpersonal Variation and Bounded Ethicality

This section provides background for our critique by describing existing tools used to predict unethicality based on interpersonal variation. Such a prediction strategy is based on the idea that different people are not equally likely to engage in unethical conduct, and that such tendencies can be observed by researchers and regulators at the personal level. Several existing research paradigms are used to identify people who are supposedly more likely to engage in unethical behavior.

For example, researchers have found some interpersonal variation in individuals’ propensity to morally disengage.\(^\text{309}\) Celia Moore created a typology of individuals based on the likelihood of their engaging in unethical conduct in the workplace.\(^\text{310}\) One of the key elements in Moore’s model is propensity to make excuses to justify harming others.\(^\text{311}\) This typology is based on Bandura’s well-known concept of moral disengagement.\(^\text{312}\) Similarly, Reynolds et al. demonstrate a moderate correlation between moral disengagement and traits such as Machiavellianism and cognitive moral development.\(^\text{313}\)

A related concept, moral firmness, measures people’s willingness to tolerate and justify dishonesty.\(^\text{314}\) Shalvi & Leiser have found some variance among individuals in their levels of moral firmness, depending on, among other things, their upbringing and social background.\(^\text{315}\) Similarly, Aquino’s moral identity scale, and the various studies based on it, have found that an individual’s likelihood of behaving in an unethical manner, even implicitly, varies based on the degree to which morality is a central component of his or her identity.\(^\text{316}\) Another related measure is the rule orientation scale, measuring people’s willingness to violate legal

312 Bandura, supra note 57.

315 Id.

rules. This concept aims to capture the extent to which one is willing to recognize and construct exceptions to legal rules, as opposed to viewing them as rigid categorical obligations.

Personal tendencies towards bounded ethicality might also be discerned through measures relating to individuals’ inclination to rely on intuitive or implicit judgement. For example, studies on the implicit association test (IAT) measure people’s tendency to make intuitive connections between unrelated concepts. While the IAT was not originally designed to predict unethically, it has since been used for this purpose. For example, the IAT has become the gold standard for measuring employment discrimination, such as determining whether employers associate ethnicity, for example, with qualifications for employment. This line of research suggests variations among people in terms of unethical tendencies. Similarly, research in the area of judicial decision-making has shown that the IAT score of different judges predicted their discriminatory behavior against black defendants.

Frederick’s cognitive reflection test (CRT) is another measure that may prove valuable for predicting unethically. This scale rates individuals based on the likelihood that they will use System 2 thinking to overcome System 1 reasoning. Studies using the CRT scale have focused on the correlation between an individual’s CRT grade and other behavioral measures.

2. The Inadequacy of Personality Traits as Predictors of Unethicality

Despite this rich literature on variations among people regarding their likelihood of engaging in unethical behavior, interpersonal variation is not dramatic or stable enough to allow differentiation in legal treatment. In fact, as discussed earlier, behavioral ethics findings indicate that an overwhelming percentage of individuals will behave unethically in some situations. Thus, in certain circumstances, personality traits barely contribute to differences in behavior, so interpersonal variance is largely unhelpful in focusing regulation efforts. Similarly, there is not enough research to indicate that any of the earlier mentioned scales consistently identify what types of people are likely to engage in unethical conduct in the real world.

Furthermore, even if people vary in their propensity for engaging in unethical behavior, it is unclear that such differences are readily discernable, even with the use of big data analysis. For instance, regulators may not be able to measure an individual’s IAT score or CRT grade, without having that individual sit through a specifically designed test in a lab setting. Similarly, policy makers may lack a reliable method for observing people’s rule orientation scale, degree of moral firmness, moral identity or propensity to morally disengage.

Personality prediction may be somewhat helpful in legal contexts that focus on extreme behaviors, such as determining an individual’s level of dangerousness in the criminal law context. In cases involving extremely threatening behaviors, prediction might be possible based on individual variance, because the focus is on people who rank very high on many of the relevant scales related to deviant behavior. In contrast, more common unethical acts can be committed by individuals closer to the middle of the curve in terms of personal propensities. Even with the use of big data analysis, it is not clear that we can know, prior to a given transaction, whether or not individual personality traits would matter enough to justify targeted regulation. Thus, we disagree with the approach advocated by Porat & Strahilevitz, who call for reliance on the Big Five personality traits theory in the creation of personalized legal treatment.

---

325 Ariely, supra note 60.
328 Feldman, supra note 2, at 32.
329 Porat & Strahilevitz, supra note 296, at 1418.
Finally, as mentioned above, the use of personal data as a predictor of unethicality is highly abrasive, critically violating individual privacy and autonomy norms. When state officials utilize big data analysis to police individual behavior, they not only misappropriate private information, but also undermine autonomy as they restrict if not eliminate the meaning of individuals’ choice and their ability to determine their own personal fate, regardless of the statistical risk they happen to represent.

B. The Proposed Situational Law Paradigm

Behavioral ethics research demonstrates that in many cases, unethicality is situation driven; it does not require any exceptional antisocial sentiment on the part of the perpetrator and ordinary people regularly participate in it.\footnote{ARIELY, supra note 60.} Thus, the aggregate result of experiments described by researchers is that unethicality is not limited to any specific group of people.\footnote{Id.} However, people do not always act unethically; they do so only when they can find ways to justify, excuse or ignore their conduct. In practical terms, bounded ethicality typically originates with the existence of a situational moral blind spot.

1. The Mechanics of Situational Regulation

Moral blind spots are not always operative, and their presence depends on a host of factors that can converge, creating situations in which individuals’ moral judgement is more easily impaired. Thus, some behavioral ethics experiments have identified situations in which up to 80 percent of people were found to lie.\footnote{Gerlach et al., supra note 149.} More significantly, behavioral ethics research shows that unethicality is highly predictable based on situational factors.\footnote{Dana et al., supra note 31.} Therefore, the best way to identify focal points of unethicality is by targeting suspect situations, rather than suspect individuals.

Focusing on the typical transgressor across different situations rather than on individual variation, which is based on the past behavior of individuals, offers several advantages.\footnote{Gino, supra note 1; BAZERMAN & TENBRUNSEL, supra note 37.} Because individuals have a limited ability to monitor their own behavior, situational factors play a larger role in prompting them to commit wrongdoing than is traditionally assumed in mainstream legal scholarship. Much research has been done on the connection between bounded ethicality and the situations in which it is prevalent. In their discussion of the situational factors affecting moral awareness, Tenbrunsel & Smith-Crowe conclude that an ethical
infrastructure, based on cultural and institutional factors, is related to the
level of moral awareness much more closely than are individual fac-
tors.335 In this vein, Tenbrunsel & Messick336 argue that the design of
formal and informal systems, as well as the general organizational cli-
mate, is responsible for most unethical behavior.337

Thus, to prevent and reduce unethicality, regulators need to know
more about those situations that tend to trigger unethical behavior. For
example, regulators could try to identify at what times during the day
people are more likely to behave unethically.338 Other factors include the
identity of the parties to a specific transaction, the nature of the goods or
services provided, the relationship between the parties, and whether ei-
ther of them is a repeat or a one-time player. More generally, the more
information we have about the situational causes of unethicality, the
more likely it becomes that targeted situational regulation will effectively
reduce it. The use of big data can prove invaluable for this purpose.

We suggest that big data analytics be used to identify situational
wrongdoing and then design tailored enforcement solutions to combat it,
based on predictions related to the typical transgressor in those situ-
tions. Note that the nature of the information to be analyzed here is mark-
edly different from that required by the personalized law approach. The
latter approach requires information that can be explicitly attributed to a
specific individual. Thus, a regulator may use an individual’s smartphone
use history to build a personal profile, which would then be used to con-
struct a standard of behavior specifically tailored for that individual.339
This approach obviously raises significant privacy concerns. In contrast,
a situational regulatory approach requires information relating to situa-
tions and the typical transgressor that appears in them, rather than infor-
mation regarding individuals. Regulators would need to know what
situations lead to an exceptionally high incidence of unethical behaviors,
regardless of the identity of the specific wrongdoers. Thus, they would
not gather information on specific individuals, but instead would gener-
ate data on an aggregate basis to construct, for example, an occupational
profile that provides insight into the behavior of people across certain
situations where unethical conduct might be on the rise.

tion throughout the hours of the day).
339 Porat & Strahilevitz, supra note 296, at 1438.
2. The Advantages of Situational Regulation

There are many benefits to tailoring regulation based on situational factors, instead of personal ones. As suggested earlier, a focus on individuals is unlikely to significantly improve the predictability of unethicality, because such a large proportion of people engage in such misconduct in certain circumstances. Conversely, behavioral ethics research shows that situational indicators are the strongest predictors of unethicality.

Second, the focus on situations can help prevent ethical numbing. Using ethical alerts only when they are most relevant is helpful in their retaining their force. If regulators know which situations call for misconduct, they can address problems in a targeted manner and trigger moral deliberation only when it will be most impactful. This is a significant advantage of situational differentiation over personal differentiation. If regulation were to be targeted towards specific individuals, this would result in those individuals encountering ethical alerts very frequently, thereby diluting the effectiveness of such reminders and defeating the purpose of the regulatory intervention.

Third, when focusing on the individual, we are faced with many contingency problems in every situation where more than one person is involved, which occurs in most commercial contexts. Hence, finding the best regulatory tool to deal with an individual based on his or her past behavior would be problematic. In addition, individual behavior is also contingent on its interaction with the situation, which also limits the accuracy of individual-based prediction.

Fourth, there are many more data points on situations than on individuals, particularly given the evidence-based approach of the personalized law literature. Even the analysis of a very specific type of transaction is likely to generate multiple data points on each situation, greatly increasing the likelihood that prediction will be accurate.

Fifth, the focus on the situation reduces the saliency of distributive justice concerns, because it is the context, and not the people who are being treated differently. Recommended policy changes will then be based on differences among situations and not among individuals. This is a crucial step towards mitigating the concerns regarding the discriminatory effects of data-driven law enforcement. If data-driven predictions are focused not on individuals but on situations, there is less of a concern

340 Gerlach et al., supra note 149.
341 Bazerman & Tenbrunsel, supra note 37, at 1–3 (highlighting the predictability of unethicality based on situational factors).
342 Tenbrunsel & Messick, supra note 57, at 228 (explaining the sources of ethical numbing).
343 Barocas & Selbst, supra note 293, at 672.
that data analysis will incorporate or perpetuate any prejudicial and discriminatory practices.

Sixth, the focus on the situation, not the individual, mitigates privacy concerns associated with the use of big data analytics. Privacy issues arising in this context are typically related to the ability to gather private information about specific individuals, rather than to gathering aggregate statistics, which provide data regarding the behavior of many unidentified individuals in a situation.344

CONCLUSION

This Article reconceptualises current practices of big data law enforcement and offers a novel framework for regulating bounded ethicality. By utilizing big data analytics, policy makers can predict unethicality and then deploy targeted regulatory responses in real time in order to improve ethical deliberation by potential perpetrators. The use of targeted ethical reminders can improve ethical decision-making, without running the risk of creating ethical numbing and over bombarding people with meaningless and random ethical messages. Big data analysis can also help tailor the most appropriate regulatory response to each specific case and match it to the specific bias that is creating the opportunity for unethical conduct. This Article identifies the advantages of using big data analytics as a platform for curbing bounded ethicality, and recommends important alterations in the way big data is currently used by law enforcers. Thus, we advocate a shift in the use of big data from a personalized to a situational approach. This move can render the use of big data more effective, considering behavioral ethics findings that suggest that problematic situations, or moral blind spots, are often stronger predictors of unethicality are interpersonal variations. Fortunately, this suggestion also represents a welcome change in terms of the legitimacy of the use of big data analytics by law enforcers. Thus, while the current personalized approach raises deep concerns regarding citizens’ privacy and the perpetuation of discriminatory practices, our proposed situational approach largely avoids these problems, as it does not require individualization of legal standards or a personalized focus of law enforcement efforts.
